1. a.) This minimization aims to make the difference between WTWX and X, so the difference between WX and X will be minimized.

- c) We account for these two paths by summing the upstream gradients, per the Law of total derivatives.
- d.) $\frac{\partial L}{\partial a} = a = \frac{\partial L}{\partial b}$ $\frac{\partial L}{\partial w^{T}} = \frac{\partial L}{\partial b} \cdot c^{T} = a \cdot (Wx)^{T}$ $\frac{\partial L}{\partial w} = \frac{\partial L}{\partial b} \cdot w^{T} = w^{T} \cdot a = w^{T}$ $\frac{\partial L}{\partial w} = \frac{\partial L}{\partial c} \cdot x^{T} = wax^{T}$

 $\nabla_{\mathbf{w}} \mathcal{I} = \mathbf{w}(\mathbf{w}^{\mathsf{T}} \mathbf{w}_{\mathsf{X}} - \mathbf{x}) \mathbf{x}^{\mathsf{T}} + (\mathbf{w}^{\mathsf{T}} \mathbf{w}_{\mathsf{X}} - \mathbf{x}) (\mathbf{w}_{\mathsf{X}})^{\mathsf{T}}$

two_layer_nn

February 6, 2020

0.1 This is the 2-layer neural network workbook for ECE 239AS Assignment #3

Please follow the notebook linearly to implement a two layer neural network.

Please print out the workbook entirely when completed.

We thank Serena Yeung & Justin Johnson for permission to use code written for the CS 231n class (cs231n.stanford.edu). These are the functions in the cs231n folders and code in the jupyer notebook to preprocess and show the images. The classifiers used are based off of code prepared for CS 231n as well.

The goal of this workbook is to give you experience with training a two layer neural network.

```
In [1]: import random
    import numpy as np
    from cs231n.data_utils import load_CIFAR10
    import matplotlib.pyplot as plt

    %matplotlib inline
    %load_ext autoreload
    %autoreload 2

def rel_error(x, y):
    """ returns relative error """
    return np.max(np.abs(x - y) / (np.maximum(1e-8, np.abs(x) + np.abs(y))))
```

0.2 Toy example

Before loading CIFAR-10, there will be a toy example to test your implementation of the forward and backward pass

```
def init_toy_model():
            np.random.seed(0)
            return TwoLayerNet(input_size, hidden_size, num_classes, std=1e-1)
        def init toy data():
            np.random.seed(1)
            X = 10 * np.random.randn(num_inputs, input_size)
            y = np.array([0, 1, 2, 2, 1])
            return X, y
        net = init_toy_model()
        X, y = init_toy_data()
0.2.1 Compute forward pass scores
In [4]: ## Implement the forward pass of the neural network.
        \# Note, there is a statement if y is None: return scores, which is why
        # the following call will calculate the scores.
        scores = net.loss(X)
        print('Your scores:')
        print(scores)
        print()
        print('correct scores:')
        correct_scores = np.asarray([
            [-1.07260209, 0.05083871, -0.87253915],
            [-2.02778743, -0.10832494, -1.52641362],
            [-0.74225908, 0.15259725, -0.39578548],
            [-0.38172726, 0.10835902, -0.17328274],
            [-0.64417314, -0.18886813, -0.41106892]])
        print(correct_scores)
        print()
        # The difference should be very small. We get < 1e-7
        print('Difference between your scores and correct scores:')
        print(np.sum(np.abs(scores - correct_scores)))
Your scores:
[[-1.07260209 0.05083871 -0.87253915]
 [-2.02778743 -0.10832494 -1.52641362]
 [-0.74225908 0.15259725 -0.39578548]
 [-0.38172726 0.10835902 -0.17328274]
 [-0.64417314 -0.18886813 -0.41106892]]
correct scores:
[[-1.07260209 0.05083871 -0.87253915]
 [-2.02778743 -0.10832494 -1.52641362]
```

[-0.74225908 0.15259725 -0.39578548]

```
[-0.38172726  0.10835902 -0.17328274]
[-0.64417314 -0.18886813 -0.41106892]]
Difference between your scores and correct scores:
3.381231233889892e-08
```

0.2.2 Forward pass loss

0.2.3 Backward pass

Implements the backwards pass of the neural network. Check your gradients with the gradient check utilities provided.

```
In [6]: from cs231n.gradient_check import eval_numerical_gradient

# Use numeric gradient checking to check your implementation of the backward pass.

# If your implementation is correct, the difference between the numeric and

# analytic gradients should be less than 1e-8 for each of W1, W2, b1, and b2.

loss, grads = net.loss(X, y, reg=0.05)

# these should all be less than 1e-8 or so
for param_name in grads:
    f = lambda W: net.loss(X, y, reg=0.05)[0]
    param_grad_num = eval_numerical_gradient(f, net.params[param_name], verbose=False)
    print('{} max relative error: {}'.format(param_name, rel_error(param_grad_num, grad))

W2 max relative error: 2.9632227682005116e-10

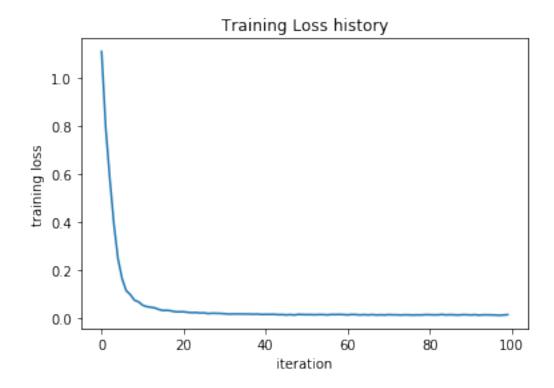

b2 max relative error: 1.2482651595953946e-09
```

W1 max relative error: 1.2832908996874818e-09 b1 max relative error: 3.1726798997101967e-09

0.2.4 Training the network

Implement neural_net.train() to train the network via stochastic gradient descent, much like the softmax and SVM.

Final training loss: 0.014497864587765884

0.3 Classify CIFAR-10

Do classification on the CIFAR-10 dataset.

```
In [8]: from cs231n.data_utils import load_CIFAR10
        def get_CIFAR10_data(num_training=49000, num_validation=1000, num_test=1000):
            Load the CIFAR-10 dataset from disk and perform preprocessing to prepare
            it for the two-layer neural net classifier. These are the same steps as
            we used for the SVM, but condensed to a single function.
            # Load the raw CIFAR-10 data
            cifar10_dir = './cifar-10-batches-py'
            X_train, y_train, X_test, y_test = load_CIFAR10(cifar10_dir)
            # Subsample the data
            mask = list(range(num_training, num_training + num_validation))
            X_val = X_train[mask]
            y_val = y_train[mask]
           mask = list(range(num_training))
           X_train = X_train[mask]
           y_train = y_train[mask]
           mask = list(range(num test))
            X test = X test[mask]
            y_test = y_test[mask]
            # Normalize the data: subtract the mean image
           mean_image = np.mean(X_train, axis=0)
            X_train -= mean_image
            X_val -= mean_image
            X_test -= mean_image
            # Reshape data to rows
            X_train = X_train.reshape(num_training, -1)
            X_val = X_val.reshape(num_validation, -1)
            X_test = X_test.reshape(num_test, -1)
            return X_train, y_train, X_val, y_val, X_test, y_test
        # Invoke the above function to get our data.
        X_train, y_train, X_val, y_val, X_test, y_test = get_CIFAR10_data()
        print('Train data shape: ', X_train.shape)
       print('Train labels shape: ', y_train.shape)
        print('Validation data shape: ', X_val.shape)
       print('Validation labels shape: ', y_val.shape)
       print('Test data shape: ', X_test.shape)
        print('Test labels shape: ', y_test.shape)
Train data shape: (49000, 3072)
Train labels shape: (49000,)
```

```
Validation data shape: (1000, 3072)
Validation labels shape: (1000,)
Test data shape: (1000, 3072)
Test labels shape: (1000,)
```

0.3.1 Running SGD

If your implementation is correct, you should see a validation accuracy of around 28-29%.

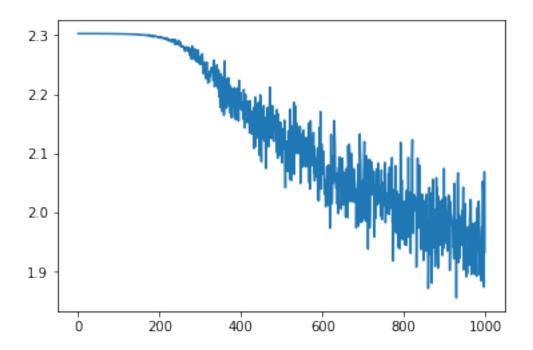

```
In [9]: input_size = 32 * 32 * 3
       hidden_size = 50
       num_classes = 10
        net = TwoLayerNet(input_size, hidden_size, num_classes)
        # Train the network
        stats = net.train(X_train, y_train, X_val, y_val,
                    num_iters=1000, batch_size=200,
                    learning_rate=1e-4, learning_rate_decay=0.95,
                    reg=0.25, verbose=True)
        # Predict on the validation set
        val_acc = (net.predict(X_val) == y_val).mean()
        print('Validation accuracy: ', val_acc)
        # Save this net as the variable subopt_net for later comparison.
        subopt_net = net
iteration 0 / 1000: loss 2.302757518613176
iteration 100 / 1000: loss 2.302120159207236

0.4 Questions:

The training accuracy isn't great.

- (1) What are some of the reasons why this is the case? Take the following cell to do some analyses and then report your answers in the cell following the one below.
- (2) How should you fix the problems you identified in (1)?

```
In [10]: stats['train_acc_history']
Out[10]: [0.095, 0.15, 0.25, 0.25, 0.315]
In [11]: # ------ #
      # YOUR CODE HERE:
         Do some debugging to gain some insight into why the optimization
         isn't great.
       # Plot the loss function and train / validation accuracies
      plt.plot(stats['train_acc_history'], label='Training Accuracy')
      plt.xlabel('Epochs')
      plt.ylabel('Accuracy')
      plt.plot(stats['val_acc_history'], label='Validation Accuracy')
      plt.legend()
      plt.show()
      plt.plot(stats['loss_history'])
      plt.show()
      # ----- #
      # END YOUR CODE HERE
       # ------ #
                Training Accuracy
       0.30
                Validation Accuracy
       0.25
     Accuracy
       0.20
       0.15
       0.10
            0.0
                 0.5
                      1.0
                           1.5
                                2.0
                                     2.5
                                          3.0
                                               3.5
                                                     4.0
                               Epochs
```

0.5 Answers:

- (1) Our learning rate seems to be zigzagging, which indicates a learning rate that is too large. However, since the training and validation accuracies are still closely aligned, we may not be training long enough.
- (2) We may want to increase our learning rate decay or decrease our learning rate so that our loss function converges faster. We may also want to train for more iterations, since it seems that we have not yet overfit our training data.

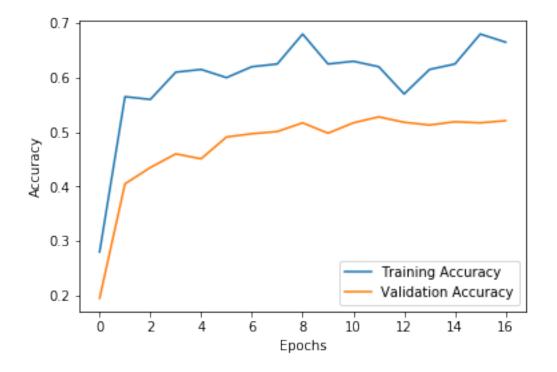

0.6 Optimize the neural network

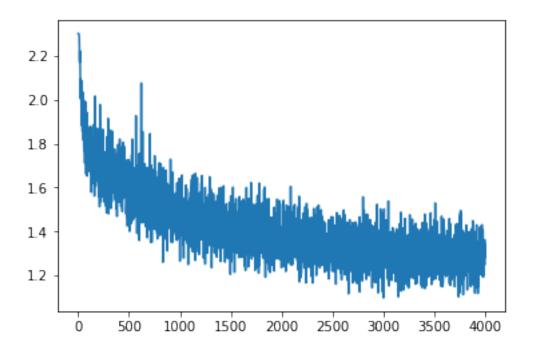

Use the following part of the Jupyter notebook to optimize your hyperparameters on the validation set. Store your nets as best_net.

In [16]: best_net = None # store the best model into this

```
Note, you need to use the same network structure (keep hidden size = 50)!
        input_size = 32 * 32 * 3
        hidden size = 50
        num classes = 10
        best net = TwoLayerNet(input size, hidden size, num classes)
        # Train the network
        stats = best_net.train(X_train, y_train, X_val, y_val,
                   num_iters=4000, batch_size=200,
                  learning_rate=3e-3, learning_rate_decay=0.85,
                  reg=0.3, verbose=True)
        # ----- #
        # END YOUR CODE HERE
        # ----- #
        val_acc = (best_net.predict(X_val) == y_val).mean()
        print('Validation accuracy: ', val_acc)
        plt.plot(stats['train_acc_history'], label='Training Accuracy')
        plt.xlabel('Epochs')
        plt.ylabel('Accuracy')
        plt.plot(stats['val_acc_history'], label='Validation Accuracy')
        plt.legend()
        plt.show()
        plt.plot(stats['loss_history'])
        plt.show()

13
14
15 class TwoLayerNet(object):
16
17
    A two-layer fully-connected neural network. The net has an input dimension
   of
    N, a hidden layer dimension of H, and performs classification over C
18
   classes.
19
    We train the network with a softmax loss function and L2 regularization on
   the
    weight matrices. The network uses a ReLU nonlinearity after the first fully
20
21
     connected layer.
22
23
     In other words, the network has the following architecture:
24
25
     input - fully connected layer - ReLU - fully connected layer - softmax
26
     The outputs of the second fully-connected layer are the scores for each
27
   class.

28
29
30
     def __init__(self, input_size, hidden_size, output_size, std=1e-4):
31
32
       Initialize the model. Weights are initialized to small random values and
33
       biases are initialized to zero. Weights and biases are stored in the
34
       variable self.params, which is a dictionary with the following keys:
35
36
       W1: First layer weights; has shape (H, D)
37
       b1: First layer biases; has shape (H,)
       W2: Second layer weights; has shape (C, H)
38
39
       b2: Second layer biases; has shape (C,)
40
41
       Inputs:
42
       - input_size: The dimension D of the input data.
       hidden_size: The number of neurons H in the hidden layer.
43
44
       output_size: The number of classes C.
45
46
       self.params = {}
       self.params['W1'] = std * np.random.randn(hidden_size, input_size)
47
       self.params['b1'] = np.zeros(hidden size)
48
       self.params['W2'] = std * np.random.randn(output_size, hidden_size)
49
50
       self.params['b2'] = np.zeros(output_size)
51
52
     def loss(self, X, y=None, reg=0.0):
53
54
       Compute the loss and gradients for a two layer fully connected neural
55
       network.
```

```
56
57
       Inputs:
58
       - X: Input data of shape (N, D). Each X[i] is a training sample.
59
       - y: Vector of training labels. y[i] is the label for X[i], and each y[i]
        an integer in the range 0 \le y[i] < C. This parameter is optional; if
60
   it
        is not passed then we only return scores, and if it is passed then we
61
        instead return the loss and gradients.
62
63

    reg: Regularization strength.

64
65
      Returns:
      If y is None, return a matrix scores of shape (N, C) where scores[i, c]
66
   is
      the score for class c on input X[i].
67
68
       If y is not None, instead return a tuple of:
69
70

    loss: Loss (data loss and regularization loss) for this batch of

   training
71
        samples.
      - grads: Dictionary mapping parameter names to gradients of those
72
73
        with respect to the loss function; has the same keys as self.params.
74
75
      # Unpack variables from the params dictionary
      W1, b1 = self.params['W1'], self.params['b1']
76
      W2, b2 = self.params['W2'], self.params['b2']

1 Fully connected networks

In the previous notebook, you implemented a simple two-layer neural network class. However, this class is not modular. If you wanted to change the number of layers, you would need to write a new loss and gradient function. If you wanted to optimize the network with different optimizers, you'd need to write new training functions. If you wanted to incorporate regularizations, you'd have to modify the loss and gradient function.

Instead of having to modify functions each time, for the rest of the class, we'll work in a more modular framework where we define forward and backward layers that calculate losses and gradients respectively. Since the forward and backward layers share intermediate values that are useful for calculating both the loss and the gradient, we'll also have these function return "caches" which store useful intermediate values.

The goal is that through this modular design, we can build different sized neural networks for various applications.

In this HW #3, we'll define the basic architecture, and in HW #4, we'll build on this framework to implement different optimizers and regularizations (like BatchNorm and Dropout).

CS231n has built a solid API for building these modular frameworks and training them, and we will use their very well implemented framework as opposed to "reinventing the wheel." This includes using their Solver, various utility functions, and their layer structure. This also includes nndl.fc_net, nndl.layers, and nndl.layer_utils. As in prior assignments, we thank Serena Yeung & Justin Johnson for permission to use code written for the CS 231n class (cs231n.stanford.edu).

1.1 Modular layers

This notebook will build modular layers in the following manner. First, there will be a forward pass for a given layer with inputs (x) and return the output of that layer (out) as well as cached variables (cache) that will be used to calculate the gradient in the backward pass.

```
def layer_forward(x, w):
    """ Receive inputs x and weights w """
    # Do some computations ...
    z = # ... some intermediate value
    # Do some more computations ...
    out = # the output

cache = (x, w, z, out) # Values we need to compute gradients
    return out, cache
```

The backward pass will receive upstream derivatives and the cache object, and will return gradients with respect to the inputs and weights, like this:

```
def layer_backward(dout, cache):
  11 11 11
  Receive derivative of loss with respect to outputs and cache,
  and compute derivative with respect to inputs.
  # Unpack cache values
 x, w, z, out = cache
  # Use values in cache to compute derivatives
 dx = # Derivative of loss with respect to x
  dw = # Derivative of loss with respect to w
 return dx, dw
In [1]: ## Import and setups
        import time
        import numpy as np
        import matplotlib.pyplot as plt
        from nndl.fc_net import *
        from cs231n.data_utils import get_CIFAR10_data
        from cs231n.gradient_check import eval_numerical_gradient, eval_numerical_gradient_arra
        from cs231n.solver import Solver
        %matplotlib inline
        plt.rcParams['figure.figsize'] = (10.0, 8.0) # set default size of plots
        plt.rcParams['image.interpolation'] = 'nearest'
        plt.rcParams['image.cmap'] = 'gray'
        # for auto-reloading external modules
        \# see http://stackoverflow.com/questions/1907993/autoreload-of-modules-in-ipython
        %load_ext autoreload
        %autoreload 2
        def rel_error(x, y):
          """ returns relative error """
          return np.max(np.abs(x - y) / (np.maximum(1e-8, np.abs(x) + np.abs(y))))
In [2]: # Load the (preprocessed) CIFAR10 data.
        data = get_CIFAR10_data()
        for k in data.keys():
          print('{}: {} '.format(k, data[k].shape))
X_train: (49000, 3, 32, 32)
y_train: (49000,)
```

```
X_val: (1000, 3, 32, 32)
y_val: (1000,)
X_test: (1000, 3, 32, 32)
y_test: (1000,)
```

1.2 Linear layers

In this section, we'll implement the forward and backward pass for the linear layers.

The linear layer forward pass is the function affine_forward in nndl/layers.py and the backward pass is affine_backward.

After you have implemented these, test your implementation by running the cell below.

1.2.1 Affine layer forward pass

Implement affine_forward and then test your code by running the following cell.

```
In [3]: # Test the affine_forward function
        num_inputs = 2
        input\_shape = (4, 5, 6)
        output_dim = 3
        input_size = num_inputs * np.prod(input_shape)
        weight_size = output_dim * np.prod(input_shape)
       x = np.linspace(-0.1, 0.5, num=input_size).reshape(num_inputs, *input_shape)
        w = np.linspace(-0.2, 0.3, num=weight_size).reshape(np.prod(input_shape), output_dim)
        b = np.linspace(-0.3, 0.1, num=output dim)
        out, _ = affine_forward(x, w, b)
        correct_out = np.array([[ 1.49834967, 1.70660132, 1.91485297],
                                [ 3.25553199, 3.5141327, 3.77273342]])
        # Compare your output with ours. The error should be around 1e-9.
        print('Testing affine_forward function:')
        print('difference: {}'.format(rel_error(out, correct_out)))
Testing affine_forward function:
difference: 9.769849468192957e-10
```

1.2.2 Affine layer backward pass

Implement affine_backward and then test your code by running the following cell.

```
In [4]: # Test the affine_backward function
x = np.random.randn(10, 2, 3)
```

```
w = np.random.randn(6, 5)
        b = np.random.randn(5)
        dout = np.random.randn(10, 5)
        dx_num = eval_numerical_gradient_array(lambda x: affine_forward(x, w, b)[0], x, dout)
        dw_num = eval_numerical_gradient_array(lambda w: affine_forward(x, w, b)[0], w, dout)
        db num = eval numerical gradient array(lambda b: affine forward(x, w, b)[0], b, dout)
        _, cache = affine_forward(x, w, b)
        dx, dw, db = affine_backward(dout, cache)
        # The error should be around 1e-10
        print('Testing affine_backward function:')
        print('dx error: {}'.format(rel_error(dx_num, dx)))
        print('dw error: {}'.format(rel_error(dw_num, dw)))
       print('db error: {}'.format(rel_error(db_num, db)))
Testing affine_backward function:
dx error: 3.771222131555466e-10
dw error: 3.4224790236683927e-09
db error: 9.60656250860874e-12
```

1.3 Activation layers

In this section you'll implement the ReLU activation.

1.3.1 ReLU forward pass

Implement the relu_forward function in nndl/layers.py and then test your code by running the following cell.

```
In [5]: # Test the relu_forward function
        x = np.linspace(-0.5, 0.5, num=12).reshape(3, 4)
        out, _ = relu_forward(x)
        correct_out = np.array([[ 0.,
                                               0.,
                                                                         0.,
                                                                                    ],
                                                            0.04545455, 0.13636364.].
                                               0.,
                                [ 0.22727273, 0.31818182, 0.40909091, 0.5,
                                                                                    ]])
        # Compare your output with ours. The error should be around 1e-8
        print('Testing relu_forward function:')
        print('difference: {}'.format(rel_error(out, correct_out)))
Testing relu_forward function:
difference: 4.999999798022158e-08
```

1.3.2 ReLU backward pass

Implement the relu_backward function in nndl/layers.py and then test your code by running the following cell.

1.4 Combining the affine and ReLU layers

Often times, an affine layer will be followed by a ReLU layer. So let's make one that puts them together. Layers that are combined are stored in nndl/layer_utils.py.

1.4.1 Affine-ReLU layers

We've implemented affine_relu_forward() and affine_relu_backward in nndl/layer_utils.py. Take a look at them to make sure you understand what's going on. Then run the following cell to ensure its implemented correctly.

In [7]: from nndl.layer_utils import affine_relu_forward, affine_relu_backward

```
x = np.random.randn(2, 3, 4)
w = np.random.randn(12, 10)
b = np.random.randn(10)
dout = np.random.randn(2, 10)

out, cache = affine_relu_forward(x, w, b)
dx, dw, db = affine_relu_backward(dout, cache)

dx_num = eval_numerical_gradient_array(lambda x: affine_relu_forward(x, w, b)[0], x, data
```

dw_num = eval_numerical_gradient_array(lambda w: affine_relu_forward(x, w, b)[0], w, do

```
db_num = eval_numerical_gradient_array(lambda b: affine_relu_forward(x, w, b)[0], b, define_relu_forward and affine_relu_backward:')
print('dx error: {}'.format(rel_error(dx_num, dx)))
print('dw error: {}'.format(rel_error(dw_num, dw)))
print('db error: {}'.format(rel_error(db_num, db)))
```

```
Testing affine_relu_forward and affine_relu_backward: dx error: 1.1103532464208299e-10 dw error: 1.7216726870718686e-10 db error: 7.826682727335577e-12
```

1.5 Softmax and SVM losses

You've already implemented these, so we have written these in layers.py. The following code will ensure they are working correctly.

```
In [8]: num_classes, num_inputs = 10, 50
        x = 0.001 * np.random.randn(num_inputs, num_classes)
        y = np.random.randint(num_classes, size=num_inputs)
        dx_num = eval_numerical_gradient(lambda x: svm_loss(x, y)[0], x, verbose=False)

1.6 Implementation of a two-layer NN

In nndl/fc_net.py, implement the class TwoLayerNet which uses the layers you made here. When you have finished, the following cell will test your implementation.

```
std = 1e-2
model = TwoLayerNet(input_dim=D, hidden_dims=H, num_classes=C, weight_scale=std)
print('Testing initialization ... ')
W1_std = abs(model.params['W1'].std() - std)
b1 = model.params['b1']
W2 std = abs(model.params['W2'].std() - std)
b2 = model.params['b2']
assert W1_std < std / 10, 'First layer weights do not seem right'
assert np.all(b1 == 0), 'First layer biases do not seem right'
assert W2_std < std / 10, 'Second layer weights do not seem right'
assert np.all(b2 == 0), 'Second layer biases do not seem right'
print('Testing test-time forward pass ... ')
model.params['W1'] = np.linspace(-0.7, 0.3, num=D*H).reshape(D, H)
model.params['b1'] = np.linspace(-0.1, 0.9, num=H)
model.params['W2'] = np.linspace(-0.3, 0.4, num=H*C).reshape(H, C)
model.params['b2'] = np.linspace(-0.9, 0.1, num=C)
X = np.linspace(-5.5, 4.5, num=N*D).reshape(D, N).T
scores = model.loss(X)
correct scores = np.asarray(
  [[11.53165108, 12.2917344, 13.05181771, 13.81190102, 14.57198434, 15.33206765,
   [12.05769098, 12.74614105, 13.43459113, 14.1230412, 14.81149128, 15.49994135,
   [12.58373087, 13.20054771, 13.81736455, 14.43418138, 15.05099822, 15.66781506,
scores_diff = np.abs(scores - correct_scores).sum()
assert scores_diff < 1e-6, 'Problem with test-time forward pass'
print('Testing training loss (no regularization)')
y = np.asarray([0, 5, 1])
loss, grads = model.loss(X, y)
correct_loss = 3.4702243556
assert abs(loss - correct_loss) < 1e-10, 'Problem with training-time loss'

1.7 Solver

We will now use the cs231n Solver class to train these networks. Familiarize yourself with the API in cs231n/solver.py. After you have done so, declare an instance of a TwoLayerNet with 200 units and then train it with the Solver. Choose parameters so that your validation accuracy is at least 50%.

```
In [10]: model = TwoLayerNet()
      solver = None
      # ----- #
      # YOUR CODE HERE:
        Declare an instance of a TwoLayerNet and then train
        it with the Solver. Choose hyperparameters so that your validation
        accuracy is at least 50%. We won't have you optimize this further
        since you did it in the previous notebook.
      solver = Solver(model, data,
                update rule='sgd',
                optim_config={
                   'learning_rate': 1e-3,
                },
                lr_decay=0.95,
                num_epochs=10, batch_size=100,
                print_every=100)
      solver.train()
      # END YOUR CODE HERE
      # ----- #

 7 This code was originally written for CS 231n at Stanford University
 8 (cs231n.stanford.edu). It has been modified in various areas for use in the
 9 ECE 239AS class at UCLA. This includes the descriptions of what code to
10 implement as well as some slight potential changes in variable names to be
11 consistent with class nomenclature. We thank Justin Johnson & Serena Yeung
12 permission to use this code. To see the original version, please visit
13 cs231n.stanford.edu.
14 | """
15
16 class TwoLayerNet(object):
17
18
    A two-layer fully-connected neural network with ReLU nonlinearity and
    softmax loss that uses a modular layer design. We assume an input dimension
19
20
    of D, a hidden dimension of H, and perform classification over C classes.
21
22
    The architecure should be affine - relu - affine - softmax.
23
24
    Note that this class does not implement gradient descent; instead, it
25
    will interact with a separate Solver object that is responsible for running
26
    optimization.
27
28
    The learnable parameters of the model are stored in the dictionary
29
    self.params that maps parameter names to numpy arrays.
30
31
32
    def __init__(self, input_dim=3*32*32, hidden_dims=100, num_classes=10,
33
                 dropout=0, weight_scale=1e-3, reg=0.0):
      1111111
34
35
      Initialize a new network.
36
37
      Inputs:
38
      - input_dim: An integer giving the size of the input
39
      - hidden_dims: An integer giving the size of the hidden layer
40
      - num_classes: An integer giving the number of classes to classify
      - dropout: Scalar between 0 and 1 giving dropout strength.
41
42
      - weight_scale: Scalar giving the standard deviation for random
43
         initialization of the weights.
44

    reg: Scalar giving L2 regularization strength.

45
      self.params = {}
46
47
      self.reg = reg
48
49
      # ============ #
50
      # YOUR CODE HERE:
          Initialize W1, W2, b1, and b2. Store these as self.params['W1'],
51
           self.params['W2'], self.params['b1'] and self.params['b2']. The
52
          biases are initialized to zero and the weights are initialized
53
          so that each parameter has mean 0 and standard deviation
54
  weight_scale.
55
          The dimensions of W1 should be (input_dim, hidden_dim) and the
          dimensions of W2 should be (hidden_dims, num_classes)
56
57
58
```

```
59
      self.params['W1'] = weight_scale * np.random.randn(input_dim,
   hidden dims)
60
      self.params['b1'] = np.zeros(hidden_dims)
      self.params['W2'] = weight_scale * np.random.randn(hidden_dims,
61
   num classes)
      self.params['b2'] = np.zeros(num_classes)
62
63

      65
      # END YOUR CODE HERE
66
      67
68
    def loss(self, X, y=None):
69
70
      Compute loss and gradient for a minibatch of data.
71
72
      Inputs:
73
      - X: Array of input data of shape (N, d_1, ..., d_k)
74
      - y: Array of labels, of shape (N,). y[i] gives the label for X[i].
75
76
      Returns:
77
      If y is None, then run a test-time forward pass of the model and return:
78
      - scores: Array of shape (N, C) giving classification scores, where
79
        scores[i, c] is the classification score for X[i] and class c.
80
81
      If y is not None, then run a training-time forward and backward pass and
82
      return a tuple of:
83
      loss: Scalar value giving the loss
84
      - grads: Dictionary with the same keys as self.params, mapping parameter
85
       names to gradients of the loss with respect to those parameters.
      \mathbf{n}
86
      scores = None
87
88
89
      # =========== #
90
      # YOUR CODE HERE:
91
          Implement the forward pass of the two-layer neural network. Store
92
          the class scores as the variable 'scores'. Be sure to use the layers
93
          you prior implemented.
94

138
139
140 class FullyConnectedNet(object):
141
     A fully-connected neural network with an arbitrary number of hidden layers,
142
     ReLU nonlinearities, and a softmax loss function. This will also implement
143
144
     dropout and batch normalization as options. For a network with L layers,
145
     the architecture will be
146
147
     {affine - [batch norm] - relu - [dropout]} x (L - 1) - affine - softmax
148
149
     where batch normalization and dropout are optional, and the {...} block is
150
     repeated L - 1 times.
151
152
     Similar to the TwoLayerNet above, learnable parameters are stored in the
153
     self.params dictionary and will be learned using the Solver class.
154
155
156
     def __init__(self, hidden_dims, input_dim=3*32*32, num_classes=10,
157
                 dropout=0, use_batchnorm=False, reg=0.0,
158
                 weight_scale=1e-2, dtype=np.float32, seed=None):
       .....
159
160
       Initialize a new FullyConnectedNet.
161
162
       Inputs:
       hidden_dims: A list of integers giving the size of each hidden layer.
163
       - input dim: An integer giving the size of the input.
164
       - num_classes: An integer giving the number of classes to classify.
165
       - dropout: Scalar between 0 and 1 giving dropout strength. If dropout=0
166
   then
         the network should not use dropout at all.
167
       - use_batchnorm: Whether or not the network should use batch
168
   normalization.
169
       - reg: Scalar giving L2 regularization strength.
       - weight scale: Scalar giving the standard deviation for random
170
         initialization of the weights.
171
```

115

```
172

    dtype: A numpy datatype object; all computations will be performed

   using
173
         this datatype. float32 is faster but less accurate, so you should use
174
         float64 for numeric gradient checking.
175
       - seed: If not None, then pass this random seed to the dropout layers.
   This
176
         will make the dropout layers deteriminstic so we can gradient check the
177
        model.

13
14
15 def affine_forward(x, w, b):
16
17
    Computes the forward pass for an affine (fully-connected) layer.
18
    The input x has shape (N, d_1, \ldots, d_k) and contains a minibatch of N
19
    examples, where each example x[i] has shape (d_1, \ldots, d_k). We will
20
     reshape each input into a vector of dimension D = d_1 * ... * d_k, and
21
22
    then transform it to an output vector of dimension M.
23
24
    Inputs:
25
    - x: A numpy array containing input data, of shape (N, d_1, ..., d_k)
    - w: A numpy array of weights, of shape (D, M)
26
27
    - b: A numpy array of biases, of shape (M,)
28
29
    Returns a tuple of:
